After using litmus to view previews of how my website would view on different types of email clients, and even send a test email to myself, I was able to see that some of the features I added on to the website wouldn't work on some of them, most of them when I used keyframes would not show the shaking motion and the button would not move, however it was still okay, because they could read the text anyways. The slideshow at the bottom of the email would only show up on a few of them; a lot of them didn't even show the images, some of them would only show buttons of the tabs, but not the actual image, and it appeared very differently depending on the platform. I believe it was some versions of Outlook that did not even allow images to be the background of the footer. There was a mix between emails that would show the columns stacked, and emails that would show the columns as they were on the browser. When I sent one to myself to test the email, I used Gmail to view it. I was able to see most of the email; the slideshow at the bottom was not interactive. You could just see the little buttons that were labeled with each product, but you could not see the actual presentation or interact with it anyway. The important thing was that all the text was readable and all the links work.
